# **Network Layer - Control Plane**

# **Review of Routing Algorithms**

#### Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

- network management, configuration
  - SNMP
  - NETCONF/YANG

## Making routing scalable

#### our routing study thus far - idealized

- all routers identical
- network "flat"
- ... not true in practice

#### scale: billions of destinations:

- can't store all destinations in routing tables!
- routing table exchange would swamp links!

#### administrative autonomy:

- Internet: a network of networks
- each network admin may want to control routing in its own network

### Internet approach to scalable routing

aggregate routers into regions known as "autonomous systems" (AS) (a.k.a. "domains")

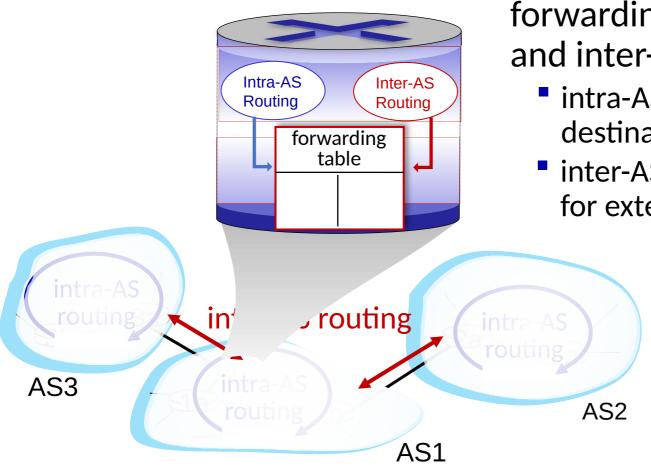

intra-AS (aka "intra-domain"): routing among within same AS ("network")

- all routers in AS must run same intradomain protocol
- routers in different AS can run different intra-domain routing protocols
- gateway router: at "edge" of its own AS, has link(s) to router(s) in other AS'es

# inter-AS (aka "inter-domain"): routing among AS'es

 gateways perform inter-domain routing (as well as intra-domain routing)

#### Interconnected ASes

forwarding table configured by intraand inter-AS routing algorithms

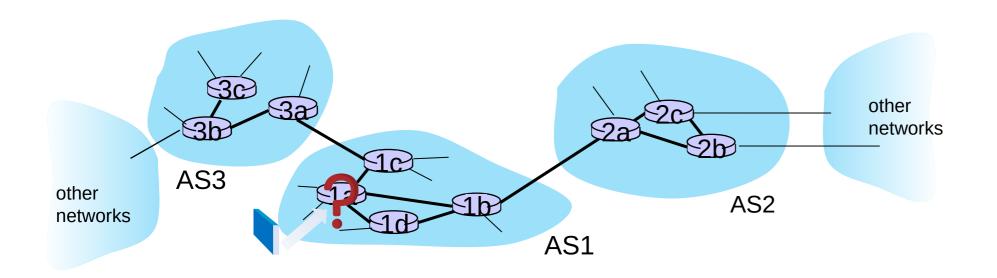

- intra-AS routing determine entries for destinations within AS
- inter-AS & intra-AS determine entries for external destinations

#### Inter-AS routing: a role in intradomain forwarding

- suppose router in AS1 receives datagram destined outside of AS1:
- router should forward packet to gateway router in AS1, but which one?

#### AS1 inter-domain routing must:

- 1. learn which destinations reachable through AS2, which through AS3
- 2. propagate this reachability info to all routers in AS1

#### Intra-AS routing: routing within an AS

#### most common intra-AS routing protocols:

- RIP: Routing Information Protocol [RFC 1723]
  - classic DV: DVs exchanged every 30 secs
  - no longer widely used
- EIGRP: Enhanced Interior Gateway Routing Protocol
  - DV based
  - formerly Cisco-proprietary for decades (became open in 2013 [RFC 7868])
- OSPF: Open Shortest Path First [RFC 2328]
  - link-state routing
  - IS-IS protocol (ISO standard, not RFC standard) essentially same as OSPF

# **OSPF (Open Shortest Path First)**routing

- "open": publicly available
- classic link-state
  - each router floods OSPF link-state advertisements (directly over IP rather than using TCP/UDP) to all other routers in entire AS
  - multiple link costs metrics possible: bandwidth, delay
  - each router has full topology, uses Dijkstra's algorithm to compute forwarding table
- security: all OSPF messages authenticated (to prevent malicious intrusion)

#### Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

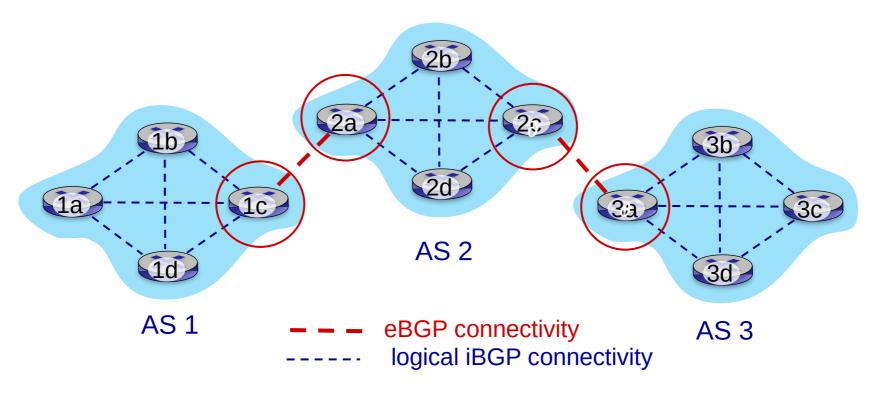

- network management, configuration
  - SNMP
  - NETCONF/YANG

# Internet inter-AS routing: BGP

- BGP (Border Gateway Protocol): the de facto inter-domain routing protocol
  - "glue that holds the Internet together"
- allows subnet to advertise its existence, and the destinations it can reach, to rest of Internet: "I am here, here is who I can reach, and how"
- BGP provides each AS a means to:
  - eBGP: obtain subnet reachability information from neighboring ASes
  - iBGP: propagate reachability information to all AS-internal routers.
  - determine "good" routes to other networks based on reachability information and policy

# eBGP, iBGP connections

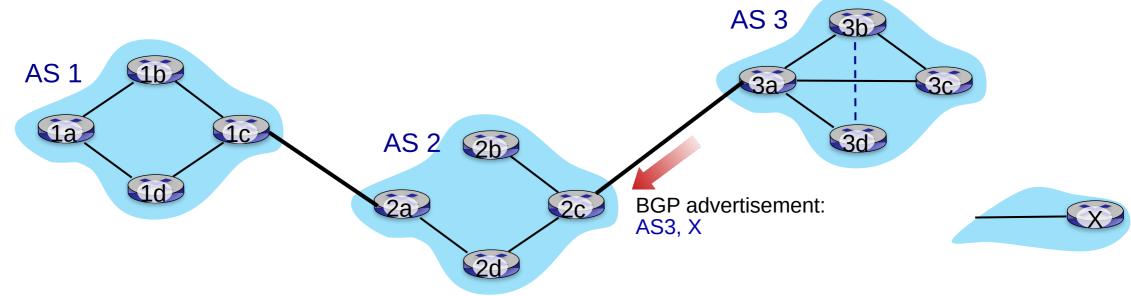

gateway routers run both eBGP and iBGP protocols

#### **BGP** basics

- BGP session: two BGP routers ("peers") exchange BGP messages over semi-permanent TCP connection:
  - advertising paths to different destination network prefixes (BGP is a "path vector" protocol)
- when AS3 gateway 3a advertises path AS3,X to AS2 gateway 2c:
  - AS3 promises to AS2 it will forward datagrams towards X

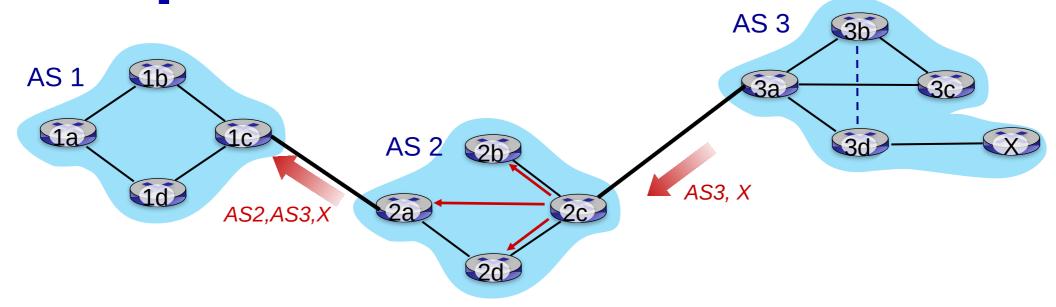

#### Path attributes and BGP routes

- BGP advertised route: prefix + attributes
  - prefix: destination being advertised
  - two important attributes:
    - AS-PATH: list of ASes through which prefix advertisement has passed
    - NEXT-HOP: indicates specific internal-AS router to next-hop AS

#### policy-based routing:

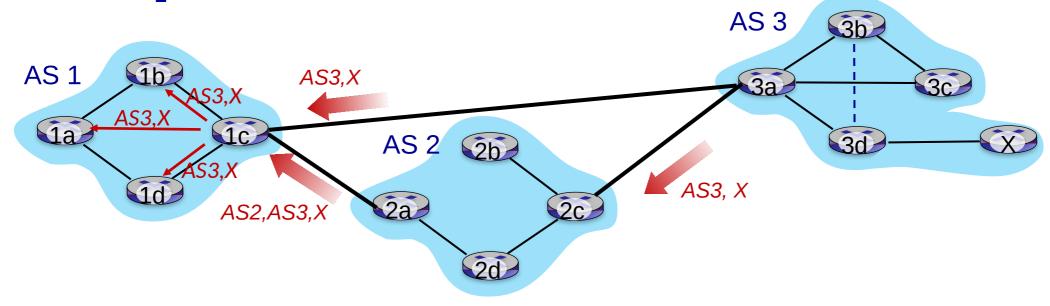

- gateway receiving route advertisement uses *import policy* to accept/decline path (e.g., never route through AS Y).
- AS policy also determines whether to advertise path to other other neighboring ASes

**BGP** path advertisement

- AS2 router 2c receives path advertisement AS3,X (via eBGP) from AS3 router 3a
- based on AS2 policy, AS2 router 2c accepts path AS3,X, propagates (via iBGP) to all AS2 routers
- based on AS2 policy, AS2 router 2a advertises (via eBGP) path AS2, AS3, X to AS1 router 1c

# BGP path advertisement (more)

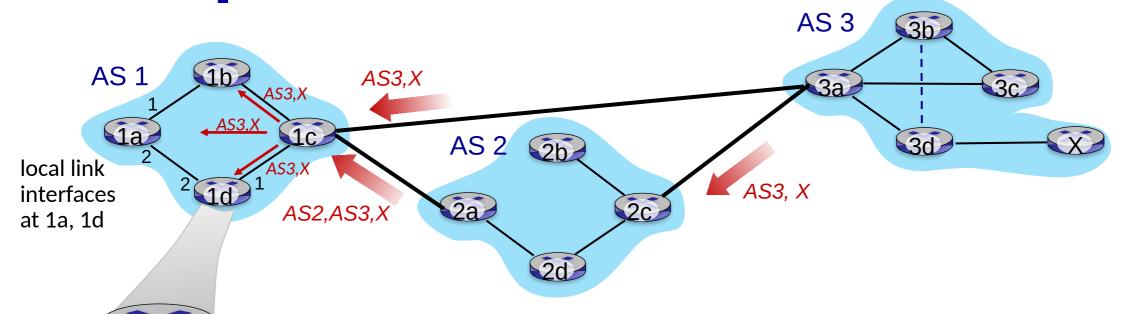

gateway router may learn about multiple paths to destination:

- AS1 gateway router 1c learns path AS2,AS3,X from 2a
- AS1 gateway router 1c learns path AS3,X from 3a
- based on policy, AS1 gateway router 1c chooses path AS3,X and advertises path within AS1 via iBGP

# **BGP** messages

- BGP messages exchanged between peers over TCP connection
- BGP messages:
  - OPEN: opens TCP connection to remote BGP peer and authenticates sending BGP peer
  - UPDATE: advertises new path (or withdraws old)
  - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs
     OPEN request
  - NOTIFICATION: reports errors in previous msg; also used to close connection

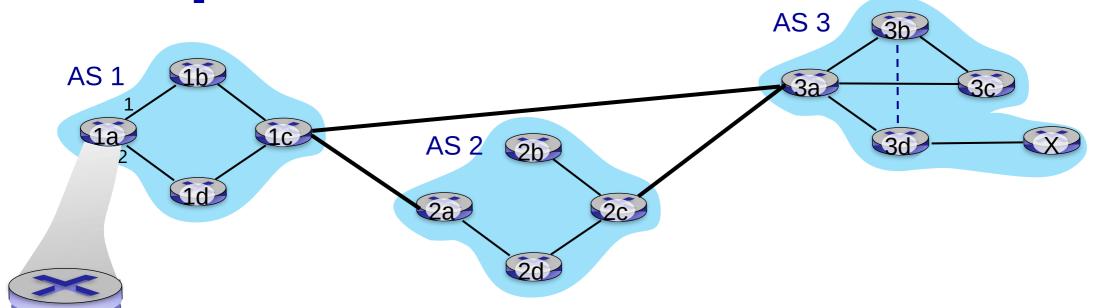

**BGP** path advertisement

| dest | interface |  |
|------|-----------|--|
|      | •••       |  |
| 1c   | 1         |  |
| X    | 1         |  |
|      |           |  |
|      |           |  |

- recall: 1a, 1b, 1d learn via iBGP from 1c: "path to X goes through 1c"
- at 1d: OSPF intra-domain routing: to get to 1c, use interface 1
- at 1d: to get to X, use interface 1

# **BGP** path advertisement

| dest | interface |
|------|-----------|
|      |           |
| 1c   | 2         |
| X    | 2         |
|      | •••       |

- recall: 1a, 1b, 1d learn via iBGP from 1c: "path to X goes through 1c"
- at 1d: OSPF intra-domain routing: to get to 1c, use interface 1
- at 1d: to get to X, use interface 1
- at 1a: OSPF intra-domain routing: to get to 1c, use interface 2
- at 1a: to get to X, use interface 2

## Why different Intra-, Inter-AS routing?

#### policy:

- inter-AS: admin wants control over how its traffic routed, who routes through its network
- intra-AS: single admin, so policy less of an issue

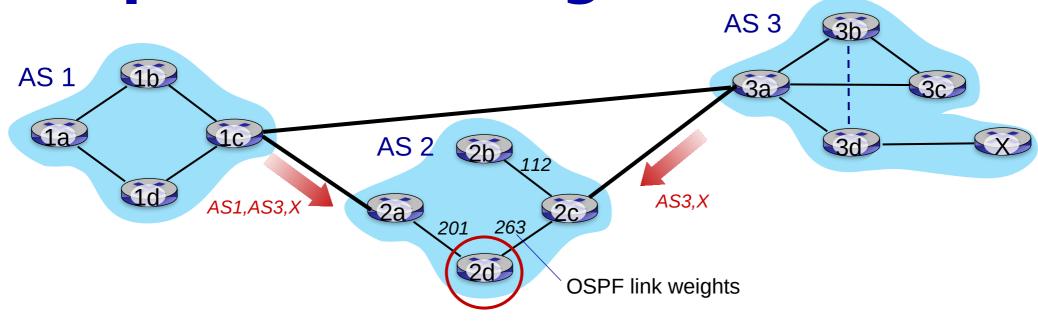

#### scale:

hierarchical routing saves table size, reduced update traffic

#### performance:

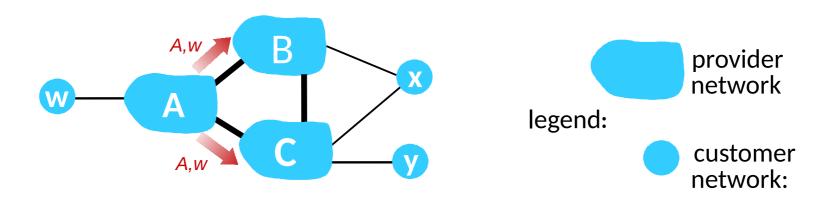

- intra-AS: can focus on performance
- inter-AS: policy dominates over performance

# Hot potato routing

- 2d learns (via iBGP) it can route to X via 2a or 2c
- hot potato routing: choose local gateway that has least intra-domain cost (e.g., 2d chooses 2a, even though more AS hops to X): don't worry about inter-domain cost!

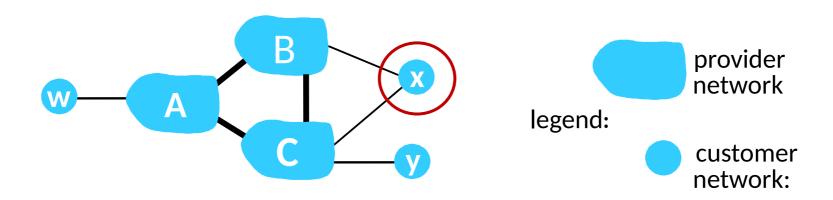

#### **BGP:** achieving policy via advertisements

ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs – a typical "real world" policy)

- A advertises path Aw to B and to C
- B chooses not to advertise BAw to C!
  - B gets no "revenue" for routing CBAw, since none of C, A, w are B's customers
  - C does not learn about CBAw path
- C will route CAw (not using B) to get to w

#### **BGP:** achieving policy via advertisements (more)

ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs – a typical "real world" policy)

- A,B,C are provider networks
- x,w,y are customer (of provider networks)
- x is dual-homed: attached to two networks
- policy to enforce: x does not want to route from B to C via x
  - .. so x will not advertise to B a route to C

#### **BGP** route selection

- router may learn about more than one route to destination AS, selects route based on:
  - 1. local preference value attribute: policy decision
  - 2. shortest AS-PATH
  - 3. closest NEXT-HOP router: hot potato routing
  - 4. additional criteria

#### Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

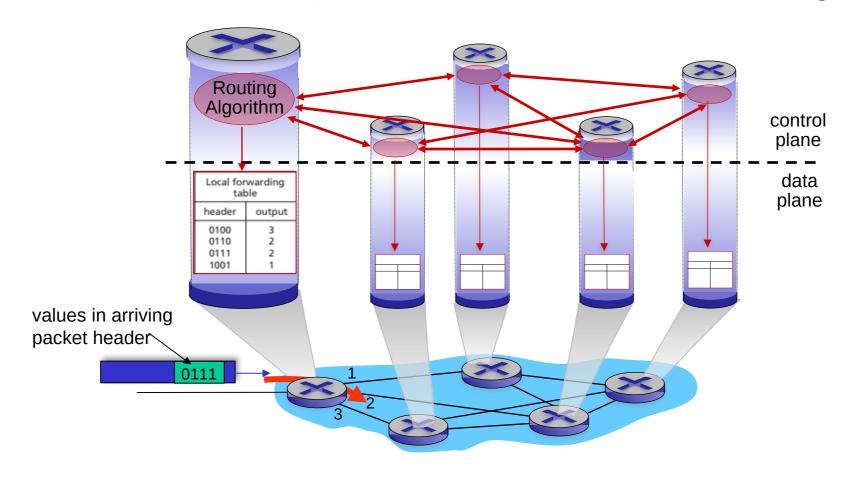

- network management, configuration
  - SNMP
  - NETCONF/YANG

- Internet network layer: historically implemented via distributed, per-router control approach:
  - monolithic router contains switching hardware, runs proprietary implementation of Internet standard protocols (IP, RIP, IS-IS, OSPF, BGP) in proprietary router OS (e.g., Cisco IOS)
  - different "middleboxes" for different network layer functions: firewalls, load balancers, NAT boxes, ..
- ~2005: renewed interest in rethinking network control plane

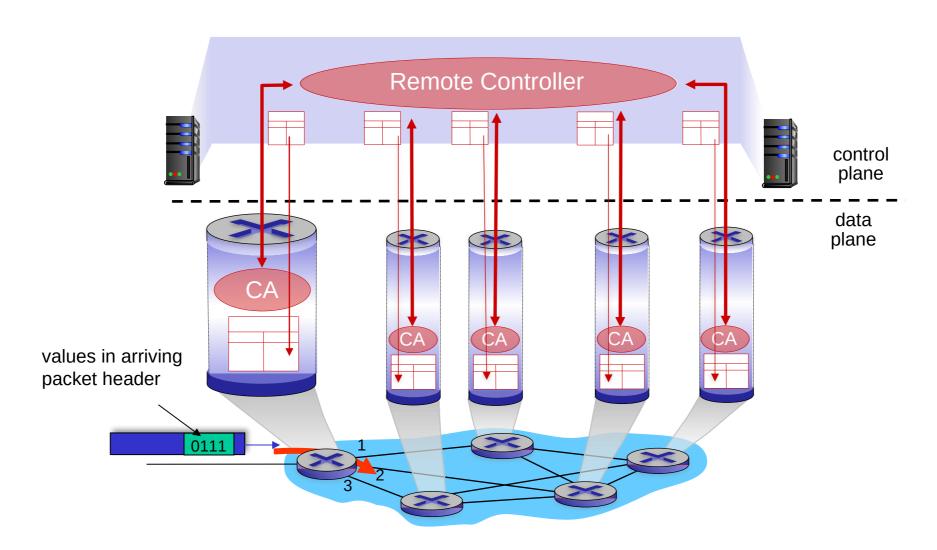

# Per-router control plane

Individual routing algorithm components in each and every router interact in the control plane to computer forwarding tables

# Software-Defined Networking (SDN) control plane

Remote controller computes, installs forwarding tables in routers

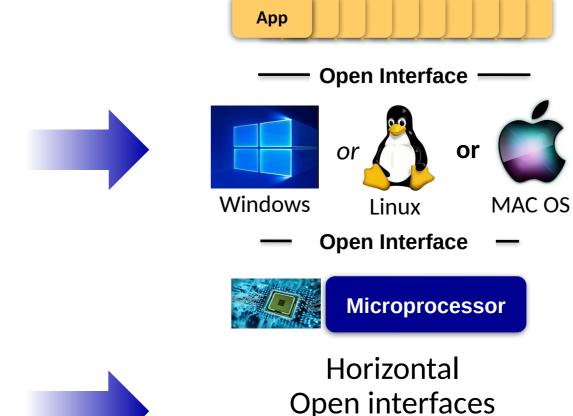

#### Why a logically centralized control plane?

- easier network management: avoid router misconfigurations, greater flexibility of traffic flows
- table-based forwarding (recall OpenFlow API) allows "programming" routers
  - centralized "programming" easier: compute tables centrally and distribute
  - distributed "programming" more difficult: compute tables as result of distributed algorithm (protocol) implemented in each-and-every router
- open (non-proprietary) implementation of control plane
  - foster innovation: let 1000 flowers bloom

#### SDN analogy: mainframe to PC revolution

Vertically integrated Closed, proprietary Slow innovation Small industry

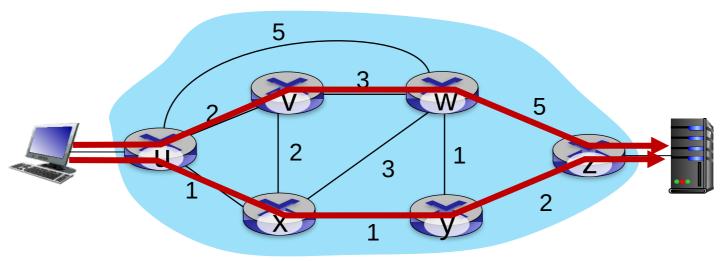

Rapid innovation

Huge industry

Network Layer: 5-30

# Traffic engineering: difficult with traditional routing

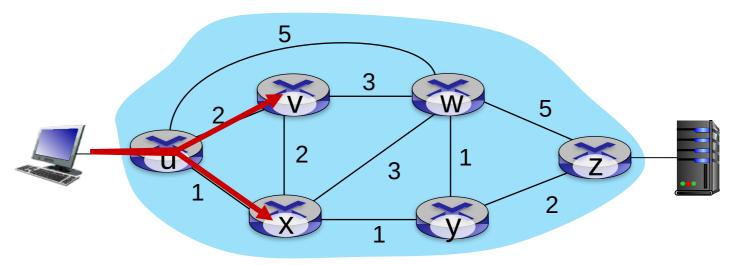

Q: what if network operator wants u-to-z traffic to flow along uvwz, rather than uxyz?

<u>A:</u> need to re-define link weights so traffic routing algorithm computes routes accordingly (or need a new routing algorithm)!

link weights are only control "knobs": not much control!

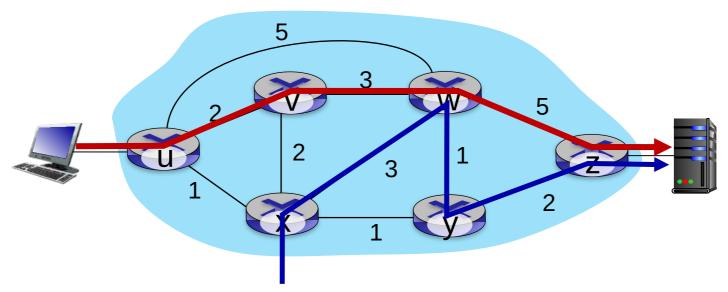

# Traffic engineering: difficult with traditional routing

Q: what if network operator wants to split u-to-z traffic along uvwz and uxyz (load balancing)?

A: can't do it (or need a new routing algorithm)

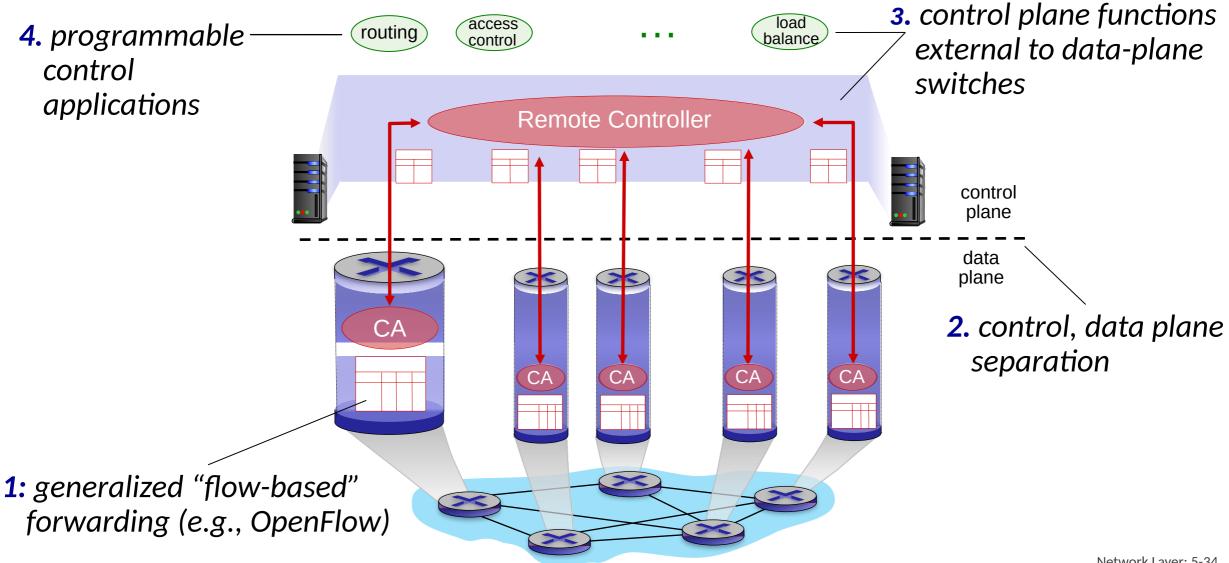

# Traffic engineering: difficult with traditional routing

Q: what if w wants to route blue and red traffic differently from w to z?

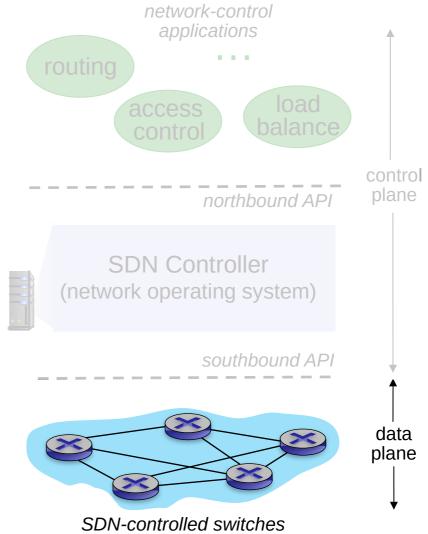

A: can't do it (with destination-based forwarding, and LS, DV routing)

We learned in Chapter 4 that generalized forwarding and SDN can be used to achieve *any* routing desired

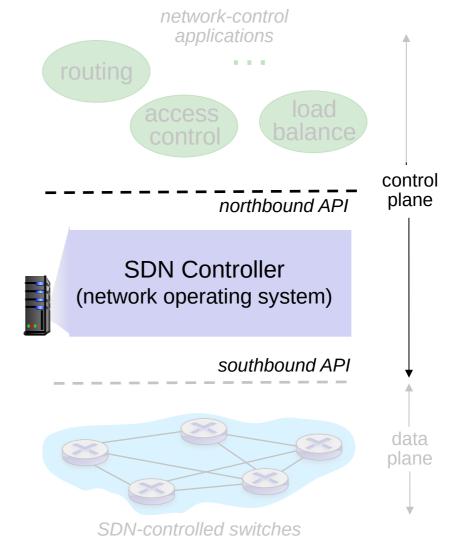

#### Data-plane switches:

- fast, simple, commodity switches implementing generalized data-plane forwarding (Section 4.4) in hardware
- flow (forwarding) table computed, installed under controller supervision
- API for table-based switch control (e.g., OpenFlow)
  - defines what is controllable, what is not
- protocol for communicating with controller (e.g., OpenFlow)

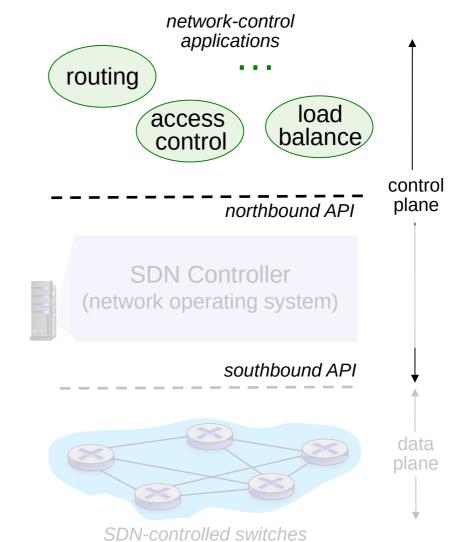

#### SDN controller (network OS):

- maintain network state information
- interacts with network control applications "above" via northbound API
- interacts with network switches "below" via southbound API
- implemented as distributed system for performance, scalability, faulttolerance, robustness

#### network-control apps:

- "brains" of control: implement control functions using lowerlevel services, API provided by SDN controller
- unbundled: can be provided by 3<sup>rd</sup> party: distinct from routing vendor, or SDN controller

# Components of SDN controller

interface layer to network control apps: abstractions API

network-wide state

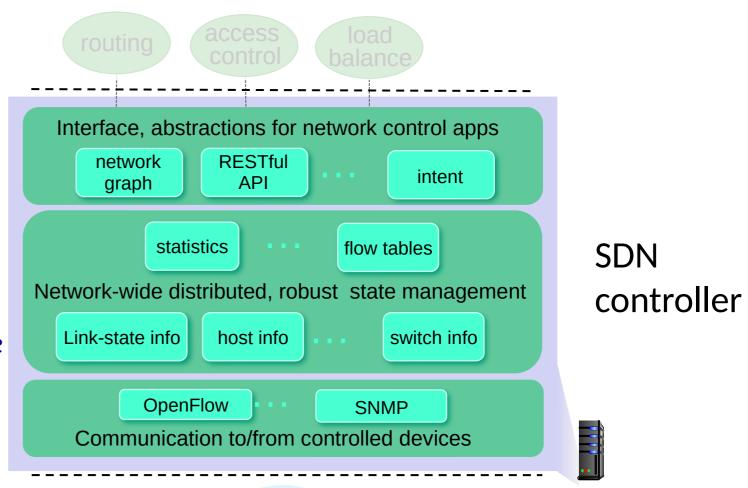

management: state of

networks links, switches,

services: a distributed database

communication: communicate between SDN controller and

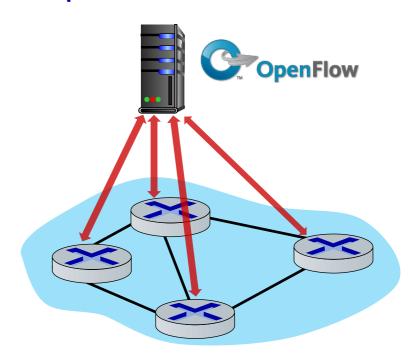

controlled switches

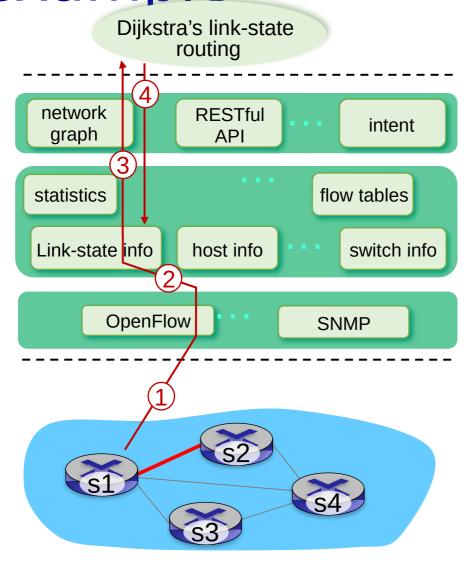

# OpenFlow protocol

- operates between controller, switch
- TCP used to exchange messages
  - optional encryption
- three classes of OpenFlow messages:
  - controller-to-switch
  - asynchronous (switch to controller)
  - symmetric (misc.)
- distinct from OpenFlow API
  - API used to specify generalized forwarding actions

#### **OpenFlow Controller**

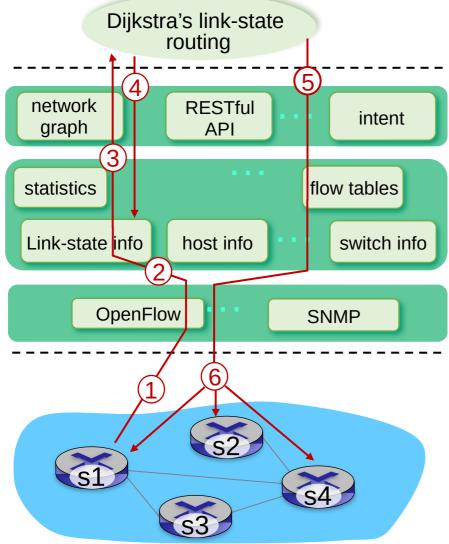

# SDN: control/data plane interaction example

- 1 S1, experiencing link failure uses OpenFlow port status message to notify controller
- 2 SDN controller receives OpenFlow message, updates link status info
- 3 Dijkstra's routing algorithm application has previously registered to be called when ever link status changes. It is called.
- Dijkstra's routing algorithm access network graph info, link state info in controller, computes new routes

# SDN: control/data plane interaction example

- 5 link state routing app interacts with flow-table-computation component in SDN controller, which computes new flow tables needed
- 6 controller uses OpenFlow to install new tables in switches that need updating

#### Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control Message Protocol

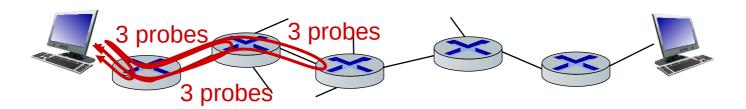

- network management, configuration
  - SNMP
  - NETCONF/YANG

### ICMP: internet control message protocol

- used by hosts and routers to communicate network-level information
  - error reporting: unreachable host, network, port, protocol
  - echo request/reply (used by ping)
- network-layer "above" IP:
  - ICMP messages carried in IP datagrams
- ICMP message: type, code plus first 8 bytes of IP datagram causing error

| <u>Type</u> | <u>Code</u> | <u>description</u>        |
|-------------|-------------|---------------------------|
| 0           | 0           | echo reply (ping)         |
| 3           | 0           | dest. network unreachable |
| 3           | 1           | dest host unreachable     |
| 3           | 2           | dest protocol unreachable |
| 3           | 3           | dest port unreachable     |
| 3           | 6           | dest network unknown      |
| 3           | 7           | dest host unknown         |
| 4           | 0           | source quench (congestion |
|             |             | control - not used)       |
| 8           | 0           | echo request (ping)       |
| 9           | 0           | route advertisement       |
| 10          | 0           | router discovery          |
| 11          | 0           | TTL expired               |
| 12          | 0           | bad IP header             |
|             |             |                           |

#### **Traceroute and ICMP**

- source sends sets of UDP segments to destination
  - 1st set has TTL = 1, 2nd set has TTL = 2, etc.
- datagram in nth set arrives to nth router:
  - router discards datagram and sends source ICMP message (type 11, code 0)
  - ICMP message possibly includes name of router & IP address
- when ICMP message arrives at source: record RTTs

#### stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

### Network layer, control plane: Done!
